**WO 01/70858 A2**(54) Title: **COMPOSITE ION EXCHANGE MATERIAL**

(57) Abstract: A composite material, for example a composite membrane for a polymer electrolyte membrane fuel cell includes a first conductive polymer and a support material for the polymer, wherein the support material comprises a second conductive polymer. A method making of the composite material is also disclosed as is its use as a polymer electrolyte membrane in a fuel cell.

COMPOSITE ION EXCHANGE MATERIAL

This invention relates to a composite ion-exchange material, for example ion-exchange membrane and provides
5 such a material per se and a method of making such a material.

One type of known polymer electrolyte membrane fuel cell (PEMFC), shown schematically in Figure 1 of the
10 accompanying diagrammatic drawings, may comprise a thin sheet 2 of a hydrogen-ion conducting Polymer Electrolyte Membrane (PEM) sandwiched on both sides by a layer 4 of platinum catalyst and an electrode 6. The layers 2, 4, 6 make up a Membrane Electrode Assembly (MEA) of less than
15 1mm thickness.

In a PEMFC, hydrogen is introduced at the anode (fuel electrode) which results in the following electrochemical reaction:

20

The hydrogen ions migrate through the conducting PEM to the cathode. Simultaneously, an oxidant is introduced at
25 the cathode (oxidant electrode) where the following electrochemical reaction takes place:

30 Thus, electrons and protons are consumed to produce water and heat. Connecting the two electrodes through an

external circuit causes an electrical current to flow in the circuit and withdraw electrical power from the cell.

The PEM 2 could comprise a single layer of ion-
5 conducting material. However, in many cases, a single layer of material does not have satisfactory mechanical properties.

Many proposals have been made for improving the
10 mechanical and other properties of ion-conducting materials for as PEMs. For example, US 5834566 (Hoechst) solves the problem by providing homogenous polymer alloys based on sulphonated polyether ketones, whereby the
15 absorption capacity for water and mechanical properties can be adjusted in a controlled manner by varying the components in the alloy and their respective ratios.

It is an object of the present invention to address problems associated with Polymer Electrolyte Membranes.

20

According to a first aspect of the invention, there is provided a composite material, for example a composite membrane, which includes a first conductive polymer and a support material for the polymer, wherein the support
25 material comprises a second conductive polymer.

Said first conductive polymer may comprise a thermoplastic or thermoset aromatic polymer, a polybenzazole or a polyaramid polymer, a perfluorinated
30 ionomer, each of which has been functionalised to provide ion-exchange sites; polystyrene sulfonic acid (PSSA), polytrifluorostyrene sulfonic acid (such as those prepared from alpha, beta, beta-trifluorostyrenes as described in

US 5422411, US 5773480 and US 5834523), polyvinyl phosphonic acid (PVPA), polyvinyl carboxylic (PVCA) acid and polyvinyl sulfonic acid (PVSA) polymers, and metal salts thereof.

5

Examples of aromatic polymers include polysulfone (PSU), polyimide (PI), polyphenylene oxide (PPO), polyphenylene sulfoxide (PPSO), polyphenylene sulfide (PPS), polyphenylene sulfide sulfone (PPS/SO₂),
 10 polyparaphenylene (PPP), polyphenylquinoxaline (PPQ), polyaryleketone and polyetherketone polymers, especially polyetherketone and polyetheretherketone polymers, for example PEK™ polymers and PEEK™ polymers respectively, from Victrex Plc.

15

Examples of perfluorinated ionomers include carboxyl-, phosphonyl- or sulphonyl-substituted perfluorinated vinyl ethers.

20 Examples of one class of preferred first conductive polymers are the polymers shown in Figures 3a to 3c when functionalised to provide ion-exchange sites.

A preferred first conductive polymer is one having a
 25 moiety of formula

and/or a moiety of formula

and/or a moiety of formula

5

wherein at least some of the units I, II and/or III are
 functionalized to provide ion-exchange sites; wherein the
 phenyl moieties in units I, II, and III are independently
 10 optionally substituted and optionally cross-linked; and
 wherein m, r, s, t, v, w and z independently represent zero or a
 positive integer, E and E' independently represent an
 oxygen or a sulphur atom or a direct link, G represents an
 oxygen or sulphur atom, a direct link or a -O-Ph-O- moiety
 15 where Ph represents a phenyl group and Ar is selected from
 one of the following moieties (i)* or (i) to (x) which is
 bonded via one or more of its phenyl moieties to adjacent
 moieties

20

In (i)*, the middle phenyl may be 1,4- or 1,3-substituted.

5 Suitably, to provide said ion exchange sites, said polymer is sulphonated, phosphorylated, carboxylated, quaternary-aminoalkylated or chloromethylated, and optionally further modified to yield $-\text{CH}_2\text{PO}_3\text{H}_2$, $-\text{CH}_2\text{NR}_3^{20+}$ where R^{20} is an alkyl, or $-\text{CH}_2\text{NAr}_3^{x+}$ where Ar^x is an aromatic
10 (arene), to provide a cation or anion exchange membrane. Further still, the aromatic moiety may contain a hydroxyl

group which can be readily elaborated by existing methods to generate $-\text{OSO}_3\text{H}$ and $-\text{OPO}_3\text{H}_2$ cationic exchange sites on the polymer. Ion exchange sites of the type stated may be provided as described in WO95/08581.

5

Preferably, said first conductive polymer is sulphonated. Preferably, the only ion-exchange sites of said first conductive polymer are sites which are sulphonated.

10

References to sulphonation include a reference to substitution with a group $-\text{SO}_3\text{M}$ wherein M stands for one or more elements selected with due consideration to ionic valencies from the following group: H, NR_4^{Y+} , in which R^Y stands for H, $\text{C}_1\text{-C}_4$ alkyl, or an alkali or alkaline earth metal or a metal of sub-group 8, preferably H, NR_4^+ , Na, K, Ca, Mg, Fe, and Pt. Preferably M represents H. Sulphonation of the type stated may be provided as described in WO96/29360.

20

Unless otherwise stated in this specification, a phenyl moiety may have 1,4- or 1,3-, especially 1,4-, linkages to moieties to which it is bonded.

25

Said first conductive polymer may include more than one different type of repeat unit of formula I; more than one different type of repeat unit of formula II; and more than one different type of repeat unit of formula III.

30

Said moieties I, II and III are suitably repeat units. In the polymer, units I, II and/or III are suitably bonded to one another - that is, with no other atoms or groups being bonded between units I, II, and III.

Where the phenyl moieties in units I, II or III are optionally substituted, they may be optionally substituted by one or more halogen, especially fluorine and chlorine, atoms or alkyl, cycloalkyl or phenyl groups. Preferred alkyl groups are C_{1-10} , especially C_{1-4} , alkyl groups. Preferred cycloalkyl groups include cyclohexyl and multicyclic groups, for example adamantyl. In some cases, the optional substituents may be used in the cross-linking of the polymer. For example, hydrocarbon optional substituents may be functionalised, for example sulphonated, to allow a cross-linking reaction to take place. Preferably, said phenyl moieties are unsubstituted.

Another group of optional substituents of the phenyl moieties in units I, II or III include alkyls, halogens, C_yF_{2y+1} where y is an integer greater than zero, $O-R^q$ (where R^q is selected from the group consisting of alkyls, perfluoralkyls and aryls), $CF=CF_2$, CN , NO_2 and OH . Trifluormethylated phenyl moieties may be preferred in some circumstances.

Where said polymer is cross-linked, it is suitably cross-linked so as to improve its properties as a polymer electrolyte membrane, for example to reduce its swellability in water. Any suitable means may be used to effect cross-linking. For example, where E represents a sulphur atom, cross-linking between polymer chains may be effected via sulphur atoms on respective chains. Alternatively, said polymer may be cross-linked via sulphonamide bridges as described in US 5 561 202. A further alternative is to effect cross-linking as described in EP-A-0008895.

However, for first conductive polymers according to the inventions described herein which are crystalline (which some are) there may be no need to effect cross-linking to produce a material which can be used as a polymer electrolyte membrane. Such polymers may be easier to
5 prepare than cross-linked polymers. Thus, said first conductive polymer of the inventions described herein may be crystalline. Preferably, said polymer is not optionally cross-linked as described.

10

Where w and/or z is/are greater than zero, the respective phenylene moieties may independently have 1,4- or 1,3-linkages to the other moieties in the repeat units of formulae II and/or III. Preferably, said phenylene
15 moieties have 1,4- linkages.

Preferably, the polymeric chain of the polymer does not include a -S- moiety. Preferably, G represents a direct link.

20

Suitably, "a" represents the mole % of units of formula I in said polymer, suitably wherein each unit I is the same; "b" represents the mole % of units of formula II in said polymer, suitably wherein each unit II is the same;
25 and "c" represents the mole % of units of formula III in said polymer, suitably wherein each unit III is the same. Preferably, a is in the range 45-100, more preferably in the range 45-55, especially in the range 48-52. Preferably, the sum of b and c is in the range 0-55, more
30 preferably in the range 45-55, especially in the range 48-52. Preferably, the ratio of a to the sum of b and c is in the range 0.9 to 1.1 and, more preferably, is about 1. Suitably, the sum of a, b and c is at least 90, preferably

at least 95, more preferably at least 99, especially about 100. Preferably, said polymer consists essentially of moieties I, II and/or III.

- 5 Said first conductive polymer may be a homopolymer having a repeat unit of general formula

or a homopolymer having a repeat unit of general formula

- 10 or a random or block copolymer of at least two different units of IV and/or V

wherein A, B, C and D independently represent 0 or 1 and E, E', G, Ar, m, r, s, t, v, w and z are as described in any
15 statement herein.

As an alternative to a first conductive polymer comprising units IV and/or V discussed above, said polymer may be a homopolymer having a repeat unit of general
20 formula

or a homopolymer having a repeat unit of general formula

5 or a random or block copolymer of at least two different units of IV* and/or V*, wherein A, B, C, and D independently represent 0 or 1 and E, E', G, Ar, m, r, s, t, v, w and z are as described in any statement herein.

10 Preferably, m is in the range 0-3, more preferably 0-2, especially 0-1. Preferably, r is in the range 0-3, more preferably 0-2, especially 0-1. Preferably t is in the range 0-3, more preferably 0-2, especially 0-1. Preferably, s is 0 or 1. Preferably v is 0 or 1.
 15 Preferably, w is 0 or 1. Preferably z is 0 or 1.

Preferably Ar is selected from the following moieties (xi)* and (xi) to (xxi):

In (xi)*, the middle phenyl may be 1,4- or 1,3-substituted.

Preferably, (xv) is selected from a 1,2-, 1,3-, or a 1,5- moiety; (xvi) is selected from a 1,6-, 2,3-, 2,6- or a 2,7- moiety; and (xvii) is selected from a 1,2-, 1,4-, 1,5-
5 , 1,8- or a 2,6- moiety.

One preferred class of first conductive polymers may include at least some ketone moieties in the polymeric chain. In such a preferred class, the polymer preferably
10 does not only include -O- and -SO₂- moieties between aryl (or other unsaturated) moieties in the polymeric chain. Thus, in this case, suitably, a polymer of the first and/or second aspects does not consist only of moieties of formula III, but also includes moieties of formula I and/or II.

15 One preferred class of first conductive polymers does not include any moieties of formula III, but suitably only includes moieties of formulae I and/or II. Where said polymer is a homopolymer or random or block copolymer as
20 described, said homopolymer or copolymer suitably includes a repeat unit of general formula IV. Such a polymer may, in some embodiments, not include any repeat unit of general formula V.

25 Suitable moieties Ar are moieties (i)*, (i), (ii), (iv) and (v) and, of these, moieties (i)*, (i), (ii) and (iv) are preferred. Preferred moieties Ar are moieties (xi)*, (xi), (xii), (xiv), (xv) and (xvi) and, of these, moieties (xi)*, (xi), (xii) and (xiv) are especially preferred.
30 Another preferred moiety is moiety (v), especially, moiety (xvi). In relation, in particular to the alternative polymers comprising units IV* and/or V*, preferred Ar moieties are (v) and, especially, (xvi).

Preferred first conductive polymers include an electron-rich, relatively non-deactivated, easily sulphonatable unit, for example a multi-phenylene moiety or a fused-rings aromatic moiety, such as naphthalene. Such an easy to sulphonate unit may be sulphonated under relatively mild conditions to introduce two sulphonate groups per unit. Thus, preferred polymers may have at least 10π electrons in a delocalized aromatic moiety. The number of π electrons may be 12 or less. Preferred polymers include a biphenylene moiety. Other preferred polymers include a naphthalene moiety. Preferred polymers include said electron rich, non-deactivated, easily sulphonatable unit bonded to two oxygen atoms. Especially preferred polymers include a -O-biphenylene-O- moiety. Other especially preferred polymers include a -O-naphthalene-O- moiety.

Preferred first conductive polymers include a first type of moiety which is relatively difficult to sulphonate and a second type of moiety which is relatively easy to sulphonate. For example, said second moiety may be sulphonatable using the relatively mild method described in Example 6 hereinafter, whereas the first moiety may be substantially non-sulphonatable in such a method. The use of the method of Example 6 may be advantageous over currently used methods which use oleum. A preferred second said moiety includes a moiety $-\text{Ph}_n-$ wherein n is an integer of at least 2. Said moiety is preferably bound to at least one ether oxygen. Especially preferred is the case wherein said moiety is $-\text{O-Ph}_n-\text{O-}$ where said ether groups are para to the Ph-Ph bond.

Preferred first conductive polymers are copolymers comprising, preferably consisting essentially of, a first repeat unit which is selected from those described below:

- 5 (a) a unit of formula IV wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m and s represent zero, w represents 1 and A and B represent 1;
- 10 (b) a unit of formula IV wherein E represents an oxygen atom, E' represents a direct link, Ar represents a moiety of structure (i), m represents zero, A represents 1, B represents zero;
- 15 (c) a unit of formula V wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m and v represent zero, z represents 1 and C and D represent 1;
- 20 (d) a unit of formula V wherein E represents an oxygen atom, E' represents a direct link, Ar represents a moiety of structure (ii), m represents 0, C represents 1, D represents 0; or
- 25 (e) a unit of formula V wherein E and E' represents an oxygen atom, Ar represents a structure (i), m represents 0, C represents 1, Z represents 1, G represents a direct link, v represents 0 and D represents 1;
- 30 Other preferred first repeat units include:

(aa) a unit of formula IV wherein E represents an oxygen atom, E' represents a direct link, Ar represents a

structure (i)*, m represents 0, A represents 1, B represents 0;

(bb) a unit of formula IV wherein E and E' represent
5 oxygen atoms, Ar represents a structure (iv), m and w represent 0, G represents a direct link, s and r represent 1, A and B represent 1;

(cc) a unit of formula IV wherein E and E' represent
10 oxygen atoms, Ar represents a structure (i), m and w represent 0, G represents a direct link, s and r represent 1, A and B represent 1;

and a second repeat unit which is selected from the
15 following:

(f) a unit of formula IV wherein E and E' represent
oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m represents 1, w represents 1, s
20 represents zero, A and B represent 1;

(g) a unit of formula IV wherein E represents an oxygen
atom, E' is a direct link, G represents a direct link, Ar represents a moiety of structure (iv), m and s represent
25 zero, w represent 1, A and B represent 1;

(h) a unit of formula V wherein E and E' represent
oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m represents 1, z represents 1, v
30 represents 0, C and D represent 1; and

(i) a unit of formula V wherein E represents an oxygen
atom, E' represents a direct link, G represents a direct

link, Ar represents a moiety of structure (iv); m and v represent zero, z represents 1, C and D represent 1;

Other second units which may form copolymers with any
5 of said first repeat units (a) to (e) (and/or with units (aa), (bb) and (cc)) above include: a unit of formula IV wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a moiety of structure (v), m represents 0, w represents 1, s represents 0, A and B
10 represent 1; or a unit of formula V wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a moiety of structure (v), m represents 0, z represents 1, v represents 0, C and D represent 1.

15 Preferred first conductive polymers for some situations may comprise first units selected from (a), (b), (c) and (e) and second units selected from (f), (g), (h) or (i). A polymer comprising units (d) and (h) may also be preferred. In some situations, first units may be selected from (aa),
20 (bb) and (cc) and second units selected from (f), (g), (h) or (i).

More preferred first conductive polymers are copolymers having a first repeat unit selected from those described
25 above, especially repeat units (b), (d) or (e) in combination with a second repeat unit selected from units (f) or (h). Other particularly preferred polymers are copolymers having a first repeat unit selected from (aa) and (bb) in combination with a second repeat unit selected
30 from units (f) or (h).

In some situations, a difficult to sulphonate unit may include at least one relatively strongly electron-

withdrawing group (e.g. -CO- or -SO₂- group) bonded to a phenyl group. Such a unit will be more difficult to sulphonate compared to, for example, a unit having a phenyl group not bonded to such a strongly electron-withdrawing group. Thus, in this case, a copolymer comprising a unit (a) or (c) in combination with difficult to sulphonate units as described may be prepared. Preferred copolymers of this type may comprise first (difficult to sulphonate) repeat unit(s) of formula (b) and/or (d) together with second relatively easy to sulphonate) unit(s) of formula (a) and/or (c). Especially preferred copolymers comprise, preferably consist essentially of a first (difficult to sulphonate) repeat unit of formula (b) or (d) together with a second (relatively easy to sulphonate) unit of formula (a) or (c).

Preferred polymers having repeat unit(s) of formulae IV* and V* may include: a unit of formula IV* wherein Ar represents a moiety of structure (v), E represents a direct link, E' represents an oxygen atom, G represents a direct link, w, s and m represent 0, A and B represent 1; and/or a repeat unit of formula V* wherein Ar represents a moiety of structure (v), E represents a direct link, E' represents an oxygen atom, G represents a direct link, z, v and m represent 0, C and D represent 1.

Said polymers having repeat units IV* and V* may include any of repeat units (a) to (i) (and/or units (aa), (bb) and (cc)) described above.

In some situations, polymers which include at least one repeat unit of formula IV or formula IV* may be preferred.

Copolymers may be prepared having one or more first repeat units and one or more of said second repeat units.

Said copolymers may be random or block copolymers.

5

Where said first conductive polymer is a copolymer as described, the mole% of co-monomer units, for example said first and second repeat units described above, may be varied to vary the solubility of the polymer in solvents, for example in organic solvents which may be used in the preparation of films and/or membranes from the polymers and/or in other solvents, especially water.

One class of first conductive polymers may comprise homopolymers, examples of which include sulphonated polyetheretherketone, polyetherketone, polyetherketoneketone, polyetheretherketoneketone, polyetherketoneetherketoneketone, polyetherdiphenyletherketone and polyether-napthalene-ether-phenyl-ketone-phenyl.

Preferred first conductive polymers suitably have a solubility of at least 10% w/v, preferably a solubility in the range 10 to 30 %w/v in a polar aprotic solvent, for example NMP, DMSO or DMF. Preferred polymers are substantially insoluble in boiling water.

First units of the type described above (with the exception of units (a) and (c)) may be relatively difficult to sulphonate, whereas second units of the type described may be easier to sulphonate.

Where a phenyl moiety is sulphonated, it may only be mono-sulphonated. However, in some situations it may be possible to effect bi- or multi-sulphonation.

5 In general terms, where a said polymer includes a -O-phenyl-O- moiety, up to 100 mole% of the phenyl moieties may be sulphonated. Where a said polymer includes a -O-biphenylene-O- moiety, up to 100 mole% of the phenyl moieties may be sulphonated. It is believed to be possible
10 to sulphonate relatively easily -O-(phenyl)_n-O- moieties wherein n is an integer, suitably 1-3, at up to 100 mole%. Moieties of formula -O-(phenyl)_n-CO- or -O-(phenyl)_n-SO₂- may also be sulphonated at up to 100 mole% but more vigorous conditions may be required. Moieties of formulae
15 -CO-(phenyl)_n-CO- and -SO₂-(phenyl)_n-SO₂- are more difficult to sulphonate and may be sulphonated to a level less than 100 mole% or not at all under some sulphonation conditions.

The glass transition temperature (T_g) of said polymer
20 may be at least 144°C, suitably at least 150°C, preferably at least 154°C, more preferably at least 160°C, especially at least 164°C. In some cases, the T_g may be at least 170°C, or at least 190°C or greater than 250°C or even 300°C.

25

Said first conductive polymer may have an inherent viscosity (IV) of at least 0.1, suitably at least 0.3, preferably at least 0.4, more preferably at least 0.6, especially at least 0.7 (which corresponds to a reduced
30 viscosity (RV) of least 0.8) wherein RV is measured at 25°C on a solution of the polymer in concentrated sulphuric acid of density 1.84gcm⁻³, said solution containing 1g of polymer per 100cm⁻³ of solution. IV is measured at 25°C on a

solution of polymer in concentrated sulphuric acid of density 1.84gcm^3 , said solution containing 0.1g of polymer per 100cm^3 of solution.

5 The measurements of both RV and IV both suitably employ a viscometer having a solvent flow time of approximately 2 minutes.

10 The main peak of the melting endotherm (T_m) for said polymer (if crystalline) may be at least 300°C .

15 In general terms, said first conductive polymer is preferably substantially stable when used as a PEM in a fuel cell. Thus, it suitably has high resistance to oxidation, reduction and hydrolysis and has very low permeability to reactants in the fuel cell. Preferably, however, it has a high proton conductivity. Furthermore, it suitably has high mechanical strength and is capable of being bonded to other components which make up a membrane
20 electrode assembly.

25 Said first conductive polymer may comprise a film, suitably having a thickness of less than 1mm, preferably less than 0.5mm, more preferably less than 0.1mm, especially less than 0.05 mm. The film may have a thickness of at least $5\mu\text{m}$.

30 Said polymer electrolyte membrane may comprise one or more layers wherein, suitably, at least one layer comprises a film of said polymer. Said membrane may have a thickness of at least $5\mu\text{m}$ and, suitably, less than 1mm, preferably less than 0.5mm, more preferably less than 0.1mm, especially less than 0.05mm.

It may be preferable for each phenyl group in a sulphonated polymer as described to be deactivated by being bonded directly to an electron withdrawing group, for example a sulphonated group, a sulphone group or a ketone group.

In one preferred embodiment, said first conductive polymer may include: polyaryletherketone and/or polyarylethersulphone units; and units of formula $-O-Ph_n-O-$ (XX) wherein Ph represents a phenyl group and n represents an integer of 2 or greater and wherein Ph groups of units (XX) are sulphonated.

The use of support material as described may allow polymers of lower equivalent weights (EW) for example less than 500 g/mol, less than 450 g/mol or even less than 400 g/mol or 370 g/mol or relatively inflexible or brittle polymers to be used in polymer electrolyte membranes.

Said first conductive polymer could be a component of a blend, wherein said blend is supported by said support material. Such a blend may include more than one type of conductive polymer, for example more than one type of first conductive polymer described herein. Alternatively, a blend may include said first conductive polymer and a non-conductive polymer. Where a blend is used, the blend suitably includes at least 45wt%, preferably at least 50wt%, more preferably at least 75wt%, especially at least 95wt% of said first conductive polymer. Preferably, said first conductive polymer is not a component of a blend, for example of the type described.

Said second conductive polymer may be selected from any of the materials described above for said first conductive polymer. Preferably, said second conductive polymer is not simply surface sulphonated but the bulk of the material is sulphonated. Thus, the concentration of ion-exchange sites is preferably not concentrated at the surface of the material but are distributed substantially throughout the material. Consequently, it is preferred to prepare said second conductive material (ie incorporating said ion-exchange sites) and then form said material into a support material, for example by casting.

The second conductive material may be distinguished from surface sulphonated materials by the conductivity. Suitably, said second conductive material has an EW of less than 2000, preferably less than 1600, more preferably less than 1200, especially less than 1000. In some cases, EW may be less than 800, 600 or even 500.

In some cases, said second conductive material may have relatively low conductivity, for example EW about 1500. In other cases, the conductivity of said second conductive material may be relatively high (e.g. EW about 300). Thus, preferably, the EW of said second conductive material is in the range 300 - 1500. More preferably, it is in the range 400 - 1000.

Said second conductive polymer preferably has at least some crystallinity - that is, it is preferably semi-crystalline.

The existence and/or extent of crystallinity in a polymer is preferably measured by wide angle X-ray

diffraction, for example as described by Blundell and Osborn (Polymer 24, 953, 1983). The assessment of crystallinity may also be undertaken using Differential Scanning Calorimetry. The level of crystallinity in said
5 second ion-conducting polymeric material may be at least 1%, is suitably at least 5%, is preferably at least 10%, is more preferably at least 15% and, especially, is at least 20% weight fraction, suitably when measured as described by Blundell and Osborn.

10

Said second conductive polymer preferably includes a repeat unit which suitably includes aromatic group containing moieties linked by -CO- and/or -Q- groups, where Q represents -O- or -S-, but does not include -SO₂- groups
15 since such would tend to render the unit amorphous. Said repeat unit preferably does not include any units whose shape and/or conformation is/are incompatible with the crystalline conformation adopted by polyetherketone units.

20 Said conductive polymer may include a second crystalline unit which is of general formula IV or IV* as described above, provided said unit is crystallisable. Suitably, to be crystallisable, said second unit does not include any Ar group of formula (ii), (viii), (ix) or (x).
25 More preferably, it may also not include an Ar group of formula (v), (vi) or (vii). Preferred Ar groups consist of one or more phenyl groups in combination with one or more carbonyl and/or ether groups.

30 Examples of crystallisable repeat units that may be included in said second conductive polymer are shown in Figure 2.

Said support material may comprise at least 30wt%, suitably at least 45wt%, preferably at least 50wt%, more preferably at least 75wt%, especially at least 95wt% of said second conductive polymer. Said support material may consist essentially of said second conductive polymer. Alternatively, said support material may comprise a blend of polymers wherein more than one type of conductive polymer is provided in the blend or a blend may include a conductive polymer of the type described and a non-conductive polymer. Examples of non-conductive polymers include polyaryletherketones and polyarylethersulphones, with specific examples being polyetheretherketone, polyetherketone and polyethersulphone.

Said composite membrane suitably incorporates a catalyst material, preferably a layer of a catalyst material which is suitably a platinum catalyst (e.g. platinum containing catalyst) or a mixture of platinum and ruthenium, on both sides of the composite membrane. Electrodes may be arranged outside the catalyst material.

Polymers having units I, II, III, IV, IV*, V and/or V* may be prepared by:

(a) polycondensing a compound of general formula

with itself wherein Y^1 represents a halogen atom or a group $-EH$ and Y^2 represents a halogen atom or, if Y^1 represents a halogen atom, Y^2 represents a group $E'H$; or

- 5 (b) polycondensing a compound of general formula

with a compound of formula

- 10 and/or with a compound of formula

- wherein Y^1 represents a halogen atom or a group $-EH$ (or $-E'H$ if appropriate) and X^1 represents the other one of a
 15 halogen atom or group $-EH$ (or $-E'H$ if appropriate) and Y^2 represents a halogen atom or a group $-E'H$ and X^2 represents the other one of a halogen atom or a group $-E'H$ (or $-EH$ if appropriate).

(c) optionally copolymerizing a product of a process as described in paragraph (a) with a product of a process as described in paragraph (b);

5 wherein the phenyl moieties of units VI, VII and/or VIII are optionally substituted; the compounds VI, VII and/or VIII are optionally sulphonated; and Ar, m, w, r, s, z, t, v, G, E and E' are as described above except that E and E' do not represent a direct link;

10

the process also optionally comprising sulphonating and/or cross-linking a product of the reaction described in paragraphs (a), (b) and/or (c) to prepare said polymer.

15 In some situations, the polymer prepared, more particularly phenyl groups thereof, may be optionally substituted with the groups hereinabove described after polymer formation.

20 Preferably, where Y^1 , Y^2 , X^1 and/or X^2 represent a halogen, especially a fluorine, atom, an activating group, especially a carbonyl or sulphone group, is arranged ortho- or para- to the halogen atom.

25 Preferred halogen atoms are fluorine and chlorine atoms, with fluorine atoms being especially preferred. Preferably, halogen atoms are arranged meta- or para- to activating groups, especially carbonyl groups.

30 Where the process described in paragraph (a) is carried out, preferably one of Y^1 and Y^2 represents a fluorine atom and the other represents an hydroxy group. More preferably in this case, Y^1 represents a fluorine atom and Y^2

represents an hydroxy group. Advantageously, the process described in paragraph (a) may be used when Ar represents a moiety of structure (i) and m represents 1.

5 When a process described in paragraph (b) is carried out, preferably, Y^1 and Y^2 each represent an hydroxy group. Preferably, X^1 and X^2 each represent a halogen atom, suitably the same halogen atom.

10 The polycondensation reactions described are suitably carried out in the presence of a base, especially an alkali metal carbonate or bicarbonate or a mixture of such bases. Preferred bases for use in the reactions include sodium carbonate and potassium carbonate and mixtures of
15 these.

The identity and/or properties of the polymers prepared in a polycondensation reaction described may be varied according to the reaction profile, the identity of
20 the base used, the temperature of the polymerisation, the solvent(s) used and the time of the polymerisation. Also, the molecular weight of a polymer prepared may be controlled by using an excess of halogen or hydroxy reactants, the excess being, for example, in the range 0.1
25 to 5.0 mole %.

In a polymer prepared in a said polycondensation reaction involving compounds of general formula VI, VII and/or VIII, moieties of general formula VI, VII and/or
30 VIII (excluding end groups Y^1 , Y^2 , X^1 and X^2) may be present in regular succession (that is, with single units of one said moiety, separated by single units of another said moiety or moieties), or semi-regular succession (that

is, with single units of one said moiety separated by strings of another moiety or moieties which are not all of the same length) or in irregular succession (that is, with at least some multiple units of one moiety separated by
5 strings of other moieties that may or may not be of equal lengths). The moieties described are suitably linked through ether or thioether groups.

Also, moieties in compounds VI, VII and/or VIII
10 arranged between a pair of spaced apart -O- atoms and which include a -phenyl-SO₂ or -phenyl-CO- bonded to one of the -O- atoms may, in the polymer formed in the polycondensation reaction, be present in regular succession, semi-regular succession or in irregular
15 succession, as described previously.

In any sampled polymer, the chains that make up the polymer may be equal or may differ in regularity from one another, either as a result of synthesis conditions or of
20 deliberate blending of separately made batches of polymer.

Compounds of general formula VI, VII and VIII are commercially available (eg from Aldrich U.K.) and/or may be prepared by standard techniques, generally involving
25 Friedel-Crafts reactions, followed by appropriate derivatisation of functional groups. The preparations of some of the monomers described herein are described in P M Hergenrother, B J Jensen and S J Havens, Polymer 29, 358 (1988), H R Kricheldorf and U Delius, Macromolecules 22,
30 517 (1989) and P A Staniland, Bull, Soc, Chem, Belg., 98 (9-10), 667 (1989).

Where compounds VI, VII and/or VIII are sulphonated, compounds of formulas VI, VII and/or VIII which are not sulphonated may be prepared and such compounds may be sulphonated prior to said polycondensation reaction.

5

Sulphonation as described herein may be carried out in concentrated sulphuric acid (suitably at least 96% w/w, preferably at least 97%w/w, more preferably at least 98%w/w; and preferably less than 98.5%w/w) at an elevated
10 temperature. For example, dried polymer may be contacted with sulphuric acid and heated with stirring at a temperature of greater than 40°C, preferably greater than 55°C, for at least one hour, preferably at least two hours, more preferably about three hours. The desired product may
15 be caused to precipitate, suitably by contact with cooled water, and isolated by standard techniques. Sulphonation may also be effected as described in US5362836 and/or EP0041780.

20 According to another aspect of the invention, there is provided a method of making a composite material, for example a composite membrane, the method comprising causing a first conductive polymer to be associated with a support material which comprises a second conductive polymer,
25 thereby to produce a composite membrane comprising said first conductive polymer and said support material.

The method preferably includes the step of contacting said first conductive polymer and said second conductive
30 polymer and subjecting the materials to treatments whereby a composite membrane in which said first and second polymers are integral parts is formed.

The method preferably includes the step of contacting the support material with a first solvent which solubilises, to some degree, the support material. Said solvent may be capable of dissolving the support material to a level of at least 5 wt%. Said solvent is preferably not a polar aprotic organic solvent, such as NMP. Said solvent is preferably a protic solvent. Said solvent preferably comprises or consists essentially of a strong acid solvent. Said solvent may comprise at least 90%, preferably at least 95%, more preferably at least 97%, especially at least 98% acid. Said strong acid solvent may be one or more of sulphuric acid, a sulphonic acid (e.g. methane sulphonic acid, trichloromethane sulphonic acid, trifluoromethane sulphonic acid), hydrofluoric acid and phosphoric acid. Said first solvent and said support material are preferably selected so that said first solvent does not functionalise the support material to provide ion-exchange sites, for example sulphonate groups. Thus, preferably, said first solvent and said support material are selected so that said first solvent does not sulphonate the support material.

In one embodiment, the method may involve said support material, suitably comprising sulphonated aromatic ether ketone polymers or copolymers or aromatic ether ketone/ether sulphone copolymers, being dissolved in said first solvent. Then, a second solvent is used to cause pores to be formed in said support material. Next, a solution which includes the first conductive polymer, suitably comprising aromatic ether ketone polymer or copolymer or aromatic ether ketone/ether sulphone copolymer, is contacted with said porous support material. A third solvent used to form the solution of the first

conductive polymer preferably does not substantially dissolve said support material. Thereafter, the third solvent is evaporated. Advantageously, the porous support material will have a low water absorption even at high
5 temperature and, accordingly, will not swell, but will retain its mechanical strength. Nevertheless, both the support material and the first conductive polymer are ion-conducting.

10 Preferably, said first solvent comprises or consists essentially of sulphuric acid. Said solvent may include at least 96%, preferably at least 98% acid. Said solvent may include less than 99% acid.

15 In general, the method preferably includes the step of contacting the support with a second solvent after said support has been contacted with said first solvent. Said second solvent is preferably arranged to cause phase inversion. Phase inversion suitably results in said
20 support material being rendered porous, suitably defining an asymmetric microporous membrane. Said second solvent is preferably a non-solvent for said support material. Preferred second solvents are aqueous; and examples include water and dilute acids.

25

Said first conductive polymer is preferably caused to penetrate pores formed in said support material. Said first conductive polymer, in a third solvent, is preferably contacted with said porous support material. Said third
30 solvent is preferably incapable of functionalising the support material to provide ion-exchange sites thereon. Said first conductive polymer may be provided as a solution in the third solvent. Where said first conductive polymer

is a component of a blend, another component or components of the blend may be substantially soluble or insoluble in the third solvent. Preferably, said support material is not substantially solubilised by said third solvent.

5 Preferably, said support material is substantially insoluble in said third solvent. Said third solvent is preferably not a strong acid. Said third solvent may be an aprotic solvent, especially a polar aprotic solvent. Said third solvent is preferably organic. It may be an alcohol

10 or a mixture of aprotic solvent and alcohol.

Where said first conductive polymer comprises moieties I, II and/or III described above, said third solvent is preferably a polar aprotic solvent, especially NMP. Where

15 said first conductive polymer is a perfluorinated ionomer then the third solvent may be an alcohol.

The ratio of the EW of the first conductive polymer to the second conductive polymer may be in the range 0.5 to 2.

20

In one embodiment, the method may involve said support material, suitably comprising polyetheretherketone, polyetherketone, polyetheretherketoneketone, polyetherketoneketone or polyetherketoneetherketoneketone,

25 sulphonated to a level at which they do not swell excessively in water, being dissolved in said first solvent. Then, the second solvent is used to cause pores to be formed in said support material. Next, a solution of the first conductive polymer, (which may be any of the

30 first conductive polymers described herein, but preferably includes moieties I, II or III described above and may be polyetheretherketone, polyetherketone, polyetheretherketoneketone, polyetherketoneketone or

polyetherketoneetherketoneketone, is contacted with said porous support material. The third solvent used to form the solution of the first conductive polymer preferably does not substantially dissolve said support material.

5 Thereafter, the third solvent is evaporated. Advantageously, the porous support material will have a low water absorption even at high temperature and, accordingly, will not swell, but will retain its mechanical strength. Nevertheless, both the support material and the first

10 conductive polymer are ion-conducting.

In another embodiment, sulphonated support material may be precipitated directly from a medium used to sulphonate an (unsulphonated) polymer which, when sulphonated,

15 provides said second conductive polymer. Thus, the method preferably includes a step of contacting an unsulphonated polymer (which when sulphonated is to provide said conductive polymer of the support material) with a sulphonating solvent (e.g. sulphuric acid) thereby

20 sulphonate the polymer. Then, the sulphonated polymer in said sulphonating solvent is laid down as a film and contacted with a solvent arranged to cause phase inversion of the film, suitably to define a microporous membrane. The microporous membrane may be impregnated with first

25 conductive polymers as described herein.

The pore size of the support material produced by phase inversion can be controlled. In this regard, said first solvent may include a small amount of a non-solvent,

30 typically less than 10% of a non-solvent, for example water or an organic liquid (e.g. acetophenone). This may impair the solvency slightly and affect the pore sizes. By producing a suitable pore size, the composite membrane may

act as a "Reverse Osmosis" membrane, allowing the passage of protons and water, but preventing the passage of organic molecules, such as methanol or hydrocarbons. A composite membrane of such a structure could reduce methanol cross-over in Direct Methanol Fuel Cells.

In an embodiment wherein the support material comprises a blend of polymers, one of which is said second conductive polymer, one of the polymers in the blend may be at least partially soluble in the third solvent which comprises the first conductive polymer. Consequently, the first conductive polymer may penetrate the support material, suitably in regions thereof which are solubilised by the third solvent. By way of example, a support material may be a blend of a second conductive polymer (which is a copolymer of sulphonated etherdiphenyletherketone and etherketone) and polyethersulphone (which is soluble in NMP). The first conductive polymer, dissolved in NMP, may be contacted with the aforesaid support material whereby the polyethersulphone thereof may be dissolved allowing penetration of the first conductive polymer into dissolved regions.

In general terms, wherein the support material comprises a blend of polymers, one of which is said second conductive polymer, said second conductive polymer and the polymer or polymers with which said second conductive polymer is blended are preferably selected so that a said first solvent used to cast the support material does not functionalise the support material to provide ion-exchange sites when contacted therewith. Examples of polymers with which said second conductive polymer may be blended include polyaryletherketones; polyarylethersulphones;

polyetheretherketone (when methane sulphonic acid is used as said first solvent); polyetherketone; and polyethersulphone (when concentrated sulphuric acid is used as said first solvent).

5

In a specific example, a blend may comprise the sulphonated polymer from Example 6a hereinafter with approximately 10wt% of polyethersulphone. The blend may be dissolved in concentrated sulphuric acid and a microporous membrane made. Thereafter, the membrane may be impregnated with an NMP solution of the sulphonated polymer from Example 6d hereinafter. In another specific example, a microporous membrane prepared from the polymer of Example 6a may be impregnated with an NMP solution of a blend comprising the sulphonated polymer from Example 6d and 10wt polyethersulphone.

The following further utilities for the composite membrane are also contemplated:

20

1. Proton exchange membrane based water electrolysis, which involves a reverse chemical reaction to that employed in hydrogen/oxygen electrochemical fuel cells.
2. Chloralkali electrolysis, typically involving the electrolysis of a brine solution to produce chlorine and sodium hydroxide, with hydrogen as a by-product.
3. Electrode separators in conventional batteries due to the chemical inertness and high electrical conductivity of the composite membranes.
4. Ion-selective electrodes, particularly those used for the potentiometric determination of a specific ion such as Ca^{2+} , Na^+ , K^+ and like ions. The composite membrane could also be employed as the sensor material for

30

humidity sensors, as the electrical conductivity of an ion exchange membrane varies with humidity.

5. Ion-exchange material for separations by ion-exchange chromatography. Typical such applications are deionization and desalination of water (for example, the purification of heavy metal contaminated water), ion separations (for example, rare-earth metal ions, trans-uranium elements), and the removal of interfering ionic species.
6. Ion-exchange membranes employed in analytical preconcentration techniques (Donnan Dialysis). This technique is typically employed in analytical chemical processes to concentrate dilute ionic species to be analysed.
7. Ion-exchange membranes in electrodialysis, in which membranes are employed to separate components of an ionic solution under the driving force of an electrical current. Electrolysis applications include the industrial-scale desalination of brackish water, preparation of boiler feed make-up and chemical process water, de-ashing of sugar solutions, deacidification of citrus juices, separation of amino acids, and the like.
8. Membranes in dialysis applications, in which solutes diffuse from one side of the membrane (the feed side) to the other side according to their concentration gradient. Separation between solutes is obtained as a result of differences in diffusion rates across the membrane arising from differences in molecular size. Such applications include hemodialysis (artificial kidneys) and the removal of alcohol from beer.
9. Membranes in gas separation (gas permeation) and pervaporation (liquid permeation) techniques.

10. Bipolar membranes employed in water splitting and subsequently in the recovery of acids and bases from waste water solutions.

5 The method may include a subsequent step of associating a catalyst material with the composite membrane prepared as described.

10 A said composite membrane described herein may be used in fuel cells or electrolyzers and, accordingly, the invention extends to a fuel cell or electrolyser incorporating a composite membrane as described. The membrane may be used in Hydrogen Fuel Cells or Direct Methanol Fuel Cells. The membrane may also be used in
15 filtration (as parts of filtration membranes), for example in ultrafiltration, microfiltration, or in reverse osmosis. The most preferred use is in a fuel cell as described.

20 Any feature of any aspect of any invention or embodiment described herein may be combined with any feature of any aspect of any other invention or embodiment described herein.

25 Specific embodiments of the invention will now be described, by way of example, with reference to Figure 1 which is a schematic representation of a polymer electrolyte membrane fuel cell; Figure 2 which shows some repeat units that may be included in conductive polymers;
30 and Figure 3 gives examples of some first conductive polymers described above.

Unless otherwise stated, all chemicals referred to hereinafter were used as received from Sigma-Aldrich Chemical Company, Dorset, U.K.

5 Example 1

A 700ml flanged flask fitted with a ground glass Quickfit lid, stirrer/stirrer guide, nitrogen inlet and outlet was charged with 4,4'-difluorobenzophenone (89.03g, 0.408 mole), 4,4'-dihydroxybiphenyl (24.58g, 0.132 mole)
10 4,4'-dihydroxybenzophenone (57.41g, 0.268 mole), and diphenylsulphone (332g) and purged with nitrogen for over 1 hour. The contents were then heated under a nitrogen blanket to between 140 and 150°C to form an almost colourless solution. While maintaining a nitrogen
15 blanket, dried sodium carbonate (43.24g, 0.408 mole) was added. The temperature was raised gradually to 315°C over 2 hours then maintained for 1 hours.

The reaction mixture was allowed to cool, milled and
20 washed with acetone and water. The resulting polymer was dried in an air oven at 120°C. The polymer had a melt viscosity at 400°C, 1000sec⁻¹ of 0.54 kNsm⁻².

Example 2

25 A 700ml flanged flask fitted with a ground glass Quickfit lid, stirrer/stirrer guide, nitrogen inlet and outlet was charged with 4,4'-difluorobenzophenone (89.03g, 0.408 mole), 4,4'-dihydroxybiphenyl (18.62g, 0.10 mole)
4,4'-dihydroxybenzophenone (64.26g, 0.30 mole), and
30 diphenylsulphone (332g) and purged with nitrogen for over 1 hour. The contents were then heated under a nitrogen blanket to between 140 and 150°C to form an almost colourless solution. While maintaining a nitrogen

blanket, dried sodium carbonate (43.24g, 0.408 mole) was added. The temperature was raised gradually to 315°C over 2 hours then maintained for 1 hours.

5 The reaction mixture was allowed to cool, milled and washed with acetone and water. The resulting polymer was dried in an air oven at 120°C. The polymer had a melt viscosity at 400°C, 1000sec⁻¹ of 0.43 kNsm⁻².

10 Example 3

A 700ml flanged flask fitted with a ground glass Quickfit lid, stirrer/stirrer guide, nitrogen inlet and outlet was charged with 4,4'-difluorobenzophenone (89.03g, 0.408 mole), hydroquinone (25.17g, 0.229 mole) 4,4'-
15 dihydroxybenzophenone (36.72g, 0.171 mole), and diphenylsulphone (332g) and purged with nitrogen for over 1 hour. The contents were then heated under a nitrogen blanket to between 140 and 150°C to form an almost colourless solution. While maintaining a nitrogen
20 blanket, dried sodium carbonate (42.44g, 0.40 mole) and dried potassium carbonate (1.11g, 0.008 mole) was added. The temperature was raised gradually to 315°C over 2 hours then maintained for 1.5 hours.

25 The reaction mixture was allowed to cool, milled and washed with acetone and water. The resulting polymer was dried in an air oven at 120°C. The polymer had a melt viscosity at 400°C, 1000sec⁻¹ of 0.39 kNsm⁻².

30 Example 4

A 700ml flanged flask fitted with a ground glass Quickfit lid, stirrer/stirrer guide, nitrogen inlet and outlet was charged with 4,4'-difluorobenzophenone (89.03g,

0.408 mole), 4,4'-dihydroxybiphenyl (29.79g, 0.16 mole)
4,4'-dihydroxydiphenylsulphone (60.06g, 0.24 mole), and
diphenylsulphone (332g) and purged with nitrogen for over 1
hour. The contents were then heated under a nitrogen
5 blanket to between 140 and 150°C to form an almost
colourless solution. While maintaining a nitrogen
blanket, dried sodium carbonate (43.24g, 0.408 mole) was
added. The temperature was raised gradually to 315°C over
3 hours then maintained for 0.5 hours.

10

The reaction mixture was allowed to cool, milled and
washed with acetone and water. The resulting polymer was
dried in an air oven at 120°C. The polymer had a melt
viscosity at 400°C, 1000sec⁻¹ of 0.6 kNsm⁻².

15

Example 5

A 700ml flanged flask fitted with a ground glass
Quickfit lid, stirrer/stirrer guide, nitrogen inlet and
outlet was charged with 4,4'-dichlorodiphenylsulphone
20 (104.25g, 0.36 mole), 4,4'-dihydroxybiphenyl (22.32g, 0.12
mole) 4,4'-dihydroxydiphenylsulphone (60.06g, 0.24 mole),
and diphenylsulphone (245g) and purged with nitrogen for
over 1 hour. The contents were then heated under a
nitrogen blanket to between 140 and 145°C to form an
25 almost colourless solution. While maintaining a nitrogen
blanket, dried potassium carbonate (50.76g, 0.37 mole) was
added. The temperature was raised to 180°C, held for 0.5
hours, raised to 205°C, held for 1 hour, raised to 225°C,
held for 2 hours, raised to 265°C, held for 0.5 hours,
30 raised to 280°C and held for 2 hours.

The reaction mixture was allowed to cool, milled and
washed with acetone/methanol (30/70) and water. The

resulting polymer was dried in an air oven at 120°C. The polymer had a Tg of 198°C and a RV of 0.52.

Example 6 - General procedure for sulphonating polymers of Examples 1 to 5

The polymers of Examples 1-5 were sulphonated by stirring each polymer in 98% sulphuric acid (3.84g polymer/100g sulphuric acid) for 21 hours at 50°C. Thereafter, the reaction solution was allowed to drip into stirred deionised water. Sulphonated polymer precipitated as free-flowing beads. Recovery was by filtration, followed by washing with deionised water until the pH was neutral and subsequent drying.

In general, ^1H nmr in DMSO- d_6 or titration confirmed that 100 mole% of the biphenyl units had sulphonated, giving one sulphonic acid group, ortho to the ether linkage, on each of the two aromatic rings comprising the biphenyl unit. The results are summarised in the table below.

Example	Polymer from Example	Theoretical EW	Measured EW
6a	1	654	6.54
6b	2	850	17.00
6c	3.00	662	662 ⁽¹⁾
6d	23.54	583	602 ⁽²⁾
6e	26.54	744	744 ⁽¹⁾

(2) Titration

Example 7 (Preparation of unreinforced membrane)

Membranes were produced from the polymer from Example 4 after sulphonation as described in Example 6 by dissolving the polymer in N-methylpyrrolidone (NMP) at a concentration of 15% w/w. The homogeneous solution was cast onto clean glass plates and then drawn down to give 400 micron films, using a stainless steel Gardner Knife. Evaporation at 100°C under vacuum for 24 hours produced membranes of mean thickness 40 microns.

10

Example 8 - General procedure for making conductive microporous membranes impregnated with conductive material

A sulphonated polymer (selected from those described in Examples 1 and 2 and sulphonated as described in Example 6) was dissolved in 98% sulphuric acid, (10%w/w) and cast onto a glass plate to produce a 100µm wet thickness coating. The plate was immersed in deionized water, removed, dried under vacuum at 105°C, thereby producing a microporous membrane. This membrane was then impregnated with a 15% (w/w) solution of the polymer prepared as described in Example 4 (and having been sulphonated as described in Example 6) in NMP to produce a wet thickness of the solution of 250µm, followed by drying for 20hrs at 105°C. The membranes prepared from the polymers described in Examples 1 and 2 are hereinafter referred to as Examples 8a and 8b respectively. The unreinforced membrane of Example 7 was highly swollen and fragile after immersion in boiling water for 1 hour, whereas the composite membranes of Examples 8a and 8b were strong and flexible.

30

Example 9 - Assessment of boiling water uptake

The following general procedure was followed to determine the boiling water uptake of membranes.

5 5cm x 5cm samples of membrane from Examples 8a, 8b and
7 having thickness as described in the table below were
separately immersed in boiling deionised water (500ml) for
60 minutes, removed and dried quickly with lint-free paper
to remove surface water, weighed, dried in an oven at 50°C
10 for 1 day, allowed to cool to ambient temperature in a
desiccator, then weighed quickly. The % water-uptakes were
calculated as described below.

$$\% \text{ Water-uptake} = \frac{\text{Wet Weight} - \text{Dry Weight}}{\text{Dry Weight}} \times 100$$

Results are provided in the table below.

Example	Reinforcing Sulphonated Microporous Membrane	Sulphonated Impregnating Ion Conducting Membrane	Mean Membrane Final dry thickness (microns)	Weight Ratio Reinforcing Sulphonated Microporous Membrane : Sulphonated Impregnating Ion Conducting Membrane	Boiling Water Uptake (%)
8a	Example 1	Example 4	60	30 : 70	146
8b	Example 2	Example 4	70	30 : 70	130
7	NA	NA	40	NA	520

Example 10

The polymer from Example 1 sulphonated as described in Example 6 was dissolved in 98% sulphuric acid then cast onto a glass plate to produce a 100 µm wet thickness
25 coating. The plate was immersed in deionized water,

removed, dried under vacuum at 105°C, thereby producing a microporous membrane. The membrane was then impregnated with a 5% (w/w) solution of Nafion (Trade Mark) (a perfluorosulphonic acid) in a mixture of lower alcohols and to produce a wet thickness of the solution of 300µm, followed by drying for 20hrs at 105°C. The unreinforced membrane was highly swollen and fragile after immersion in boiling water for 1 hour, whereas the composite membrane was strong and flexible.

10

Example 11

Polyetherketone (PEK™ -P22, Victrex plc, Melt Viscosity 0.22kNsm⁻²) and the polymer from Example 1 sulphonated as described in Example 6 were separately dissolved in 98% sulphuric acid (7%w/w), blended in a ratio 1:1 then cast onto a glass plate to produce a 150 µm wet thickness coating. The plate was immersed in deionized water, removed, dried under vacuum at 105°C, thereby producing a microporous membrane. This membrane was then impregnated with a 15% (w/w) solution of the polymer prepared as described in Example 4 (and having been sulphonated as described in Example 6) in NMP to produce a wet thickness of the solution of 250µm, followed by drying for 2hrs at 105°C. The wet unreinforced membrane was highly swollen and fragile, whereas the wet composite membrane was strong and flexible, with the boiling water uptake being 520% and 110% respectively.

25

Example 12

The polymer from Example 1 sulphonated as described in Example 6 was dissolved in 98% sulphuric acid, (10%w/w) and cast onto a glass plate to produce a 100µm wet thickness coating. The plate was immersed in deionized

30

water, removed, dried under vacuum at 105°C, thereby producing a microporous membrane. This membrane was then impregnated with a 15% (w/w) solution of the polymer prepared as described in Example 5 and having been
5 sulphonated as described in Example 6 in NMP to produce a wet thickness of the solution of 250µm, followed by drying for 20hrs at 105°C. The unreinforced membrane was highly swollen and fragile after immersion in boiling water for 1 hour, whereas the composite membrane was strong and
10 flexible.

Example 13

The polymer from Example 1, sulphonated as described in Example 6, was dissolved in 98% sulphuric acid (10%w/w)
15 and cast onto a glass plate to produce a 100µm wet thickness coating. The plate was immersed in deionized water, removed, dried under vacuum at 105°C, thereby producing a microporous membrane. This membrane was then impregnated with a 15% (w/w) solution of the polymer
20 prepared as described in Example 4 (and having been sulphonated as described in Example 6) in NMP to produce a wet thickness of the solution for Examples 13a, 13b and 13c, as described in the Table below. The unreinforced membrane (i.e. prepared from sulphonated polymer from
25 Example 4 alone, as described in Example 7) was highly swollen and fragile after immersion in boiling water for 1 hour, whereas the composite membranes of Examples 13a, b, c were strong and flexible.

Example	Sulphonated Impregnating Ion Conducting Membrane wet thickness	Mean Membrane Final dry thickness (microns)	Boiling Water Uptake (%)
Example 13a	300	75	225.00
Example 13b	300.00	40	127
Example 13c	225.00	40	103
Example 7d	525.00	40	520

Example 14 Comparison of Fuel Cell Performance of Reinforced Composite Membrane prepared in Example 8a with Unreinforced Membrane prepared in Example 7.

The reinforced composite membrane prepared in Example 8a and the unreinforced membrane prepared in Example 7 were pre-treated by boiling in 1M sulphuric acid, allowed to cool to room temperature followed by thorough washing with deionised water. Membrane Electrode Assemblies (MEA) were prepared using standard platinum loaded, Nafion® impregnated Gas Diffusion Electrodes (E-Tek, Elat 0.35mg Pt. cm⁻²) hot pressed onto the membrane. The active area being 11.8cm². The following operating conditions were followed:

Hydrogen Pressure	3Barg
Air Pressure	3Barg
Hydrogen Stoichiometry	1.5
Air Stoichiometry	3
Cell Temperature	60°C
Current Density	0.7Acm ⁻²

The comparative voltages at current density of 0.8Acm⁻² for the unreinforced and reinforced membranes were 0.64 and 0.6V respectively.

5 The MEA using the unreinforced membrane was very fragile and required very careful handling, whereas the reinforced composite membrane was robust.

Example 15

10 The polymer from Example 1 was sulphonated by stirring it in 98% sulphuric acid (7.5% w/w) for 21 hours at 50°C. Thereafter, the reaction solution was allowed to cool to room temperature, cast onto a clean glass plate and then drawn down to produce a 150µm wet thickness coating, using a stainless
15 steel Gardner Knife. The plate was immersed in deionized water, removed, dried under vacuum at 105°C, thereby producing a microporous membrane. This membrane was then impregnated with a 15% (w/w) solution of the polymer prepared as described in Example 4 (and having been
20 sulphonated as described in Example 5) in NMP to produce a wet thickness of the solution of 250µm, followed by drying for 20hrs at 105°C. The unreinforced membrane was highly swollen and fragile after immersion in boiling water for 1 hour, whereas the composite membrane was strong and
25 flexible, with Boiling Water Uptakes of 520 and 160% respectively.

The reader's attention is directed to all papers and documents which are filed concurrently with or previous to
30 this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

The invention is not restricted to the details of the foregoing embodiment(s). The invention extend to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so disclosed.

CLAIMS

1. A composite material which includes a first conductive polymer and a support material for the polymer, wherein
 5 the support material comprises a second conductive polymer.

2. A material according to claim 1, wherein said composite material is a composite membrane.

10

3. A material according to claim 1 or claim 2, wherein said first conductive polymer comprises a thermoplastic or thermoset aromatic polymer, a polybenzazole or a polyaramid polymer, or a perfluorinated ionomer, each of
 15 which has been functionalised to provide ion-exchange sites; polystyrene sulphonic acid, polytrifluorostyrene sulphonic acid, polyvinyl phosphonic acid, polyvinyl carboxylic acid and polyvinyl sulphonic acid polymers, and metal salts thereof.

20

4. A material according to any preceding claim wherein said first conductive polymer is one having a moiety of formula

25

and/or a moiety of formula

and/or a moiety of formula

5

wherein at least some of the units I, II and/or III are
 functionalized to provide ion-exchange sites; wherein the
 phenyl moieties in units I, II, and III are independently
 10 optionally substituted and optionally cross-linked; and
 wherein m, r, s, t, v, w and z independently represent zero or a
 positive integer, E and E' independently represent an
 oxygen or a sulphur atom or a direct link, G represents an
 oxygen or sulphur atom, a direct link or a -O-Ph-O- moiety
 15 where Ph represents a phenyl group and Ar is selected from
 one of the following moieties (i)* or (i) to (x) which is
 bonded via one or more of its phenyl moieties to adjacent
 moieties

20

5. A material according to any preceding claim, wherein said first conductive material is sulphonated.

5

6. A material according to any preceding claim, wherein said first conductive polymer is a homopolymer having a repeat unit of general formula

or a homopolymer having a repeat unit of general formula

5 or

a homopolymer having a repeat unit of general formula

or a homopolymer having a repeat unit of general formula

10

or a random or block copolymer of at least two different units selected from IV and V or from IV* and V*,

15 wherein A, B, C and D independently represent 0 or 1 and E, E', G, Ar, M, r, s, t, v, w and z are as described in claim 4.

7. A material according to any preceding claim, wherein said first conductive polymer includes at least some ketone moieties in the polymeric chain.
- 5
8. A material according to any preceding claim, wherein said first conductive polymer includes a multi-phenylene moiety or a fused ring aromatic moiety.
- 10 9. A material according to claim 8, wherein a said multi-phenylene moiety or fused ring aromatic moiety is bonded to two oxygen atoms.
10. A material according to any preceding claim, wherein
- 15 said first conductive polymer includes a -O-biphenylene-O- or -O-naphthalene-O- moiety.
11. A material according to any preceding claim, wherein said first conductive polymer is a copolymer comprising a
- 20 first repeat unit selected from the following:
- (a) a unit of formula IV wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m and s represent zero, w
- 25 represents 1 and A and B represent 1;
- (b) a unit of formula IV wherein E represents an oxygen atom, E' represents a direct link, Ar represents a moiety of structure (i), m represents zero, A represents 1, B
- 30 represents zero;
- (c) a unit of formula V wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a

moiety of structure (iv), m and v represent zero, z represents 1 and C and D represent 1;

(d) a unit of formula V wherein E represents an oxygen
5 atom, E' represents a direct link, Ar represents a moiety of structure (ii), m represents 0, C represents 1, D represents 0; or

(e) a unit of formula V wherein E and E' represents an
10 oxygen atom, Ar represents a structure (i), m represents 0, C represents 1, Z represents 1, G represents a direct link, v represents 0 and D represents 1;

(aa) a unit of formula IV wherein E represents an
15 oxygen atom, E' represents a direct link, Ar represents a structure (i)*, m represents 0, A represents 1, B represents 0;

(bb) a unit of formula IV wherein E and E' represent
20 oxygen atoms, Ar represents a structure (iv), m and w represent 0, G represents a direct link, s and r represent 1, A and B represent 1;

(cc) a unit of formula IV wherein E and E' represent
25 oxygen atoms, Ar represents a structure (i), m and w represent 0, G represents a direct link, s and r represent 1, A and B represent 1;

and a second repeat unit which is selected from the
30 following:

(f) a unit of formula IV wherein E and E' represent oxygen atoms, G represents a direct link, Ar represents a

moiety of structure (iv), m represents 1, w represents 1, s represents zero, A and B represent 1;

(g) a unit of formula IV wherein E represents an oxygen
5 atom, E' is a direct link, G represents a direct link, Ar represents a moiety of structure (iv), m and s represent zero, w represent 1, A and B represent 1;

(h) a unit of formula V wherein E and E' represent
10 oxygen atoms, G represents a direct link, Ar represents a moiety of structure (iv), m represents 1, z represents 1, v represents 0, C and D represent 1; and

(i) a unit of formula V wherein E represents an oxygen
15 atom, E' represents a direct link, G represents a direct link, Ar represents a moiety of structure (iv), m and v represent zero, z represents 1, C and D represent 1;

(j) a unit of formula IV wherein E and E' represent
20 oxygen atoms, G represents a direct link, Ar represents a moiety of structure (v), m represents 0, w represents 1, s represents 0, A and B represent 1;

(k) a unit of formula V wherein E and E' represent
25 oxygen atoms, G represents a direct link, Ar represents a moiety of structure (v), m represents 0, z represents 1, v represents 0, C and D represent 1.

12. A material according to any of claims 1 to 10, wherein
30 said first conductive polymer comprises a copolymer comprising a unit (a) and/or (c) as described in claim 11 in combination with a unit (b), (d), (e), (aa), (bb) and/or (cc) as described in claim 11.

13. A material according to any preceding claim, wherein said first conductive polymer has an equivalent weight (EW) of less than 500g/mol.

5

14. A material according to any preceding claim, wherein said second conductive polymer is selected from a material described for said first conductive polymer in any preceding claim.

10

15. A material according to any preceding claim, wherein said second conductive polymer has an equivalent weight (EW) of less than 2000.

15 16. A material according to any preceding claim, wherein said second conductive polymer is semi-crystalline.

17. A material according to any preceding claim, wherein said composite material incorporates a catalyst material.

20

18. A method of making a composite material, the method comprising causing a first conductive polymer to be associated with a support material which comprises a second conductive polymer, thereby to produce a composite membrane
25 comprising said first conductive polymer and said support material.

19. A method according to claim 18, which includes the step of contacting the support material with a first
30 solvent which solubilises the support material.

20. A method according to claim 19, which includes contacting the support material with a second solvent

after contact with said first solvent, wherein said second solvent is arranged to cause phase inversion to render the support material porous; and, thereafter, said first conductive polymer is caused to penetrate pores formed in
5 the support material.

21. A method according to claim 20, wherein said first conductive polymer is provided in a third solvent and then caused to penetrate said pores.

10

22. A method according to claim 18, which includes contacting an unsulphonated polymer, which when sulphonated is to provide said conductive polymer of the support material, with a sulphonating solvent thereby to
15 sulphonate the polymer; forming a film of said sulphonated polymer; contacting the film with a solvent arranged to cause phase inversion of the film, thereby to define a microporous membrane; and impregnating the microporous membrane with a first conductive polymer.

20

23. A fuel cell or electrolyser incorporating a composite material according to any of claims 1 to 17 or made in a method according to any of claims 18 to 22.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

Present claims 1 to 23 relate to an extremely large number of possible composite materials, methods, fuel cells and electrolyzers : support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT is to be found, however, for only a very small proportion of thereof. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Consequently, the search has been carried out for those parts of the claims which appear to be supported and disclosed, namely those parts relating to the use of polyarylether ketones or polyarylether sulphones described in the examples of the present application in composite materials, methods, fuel cells and electrolyzers.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
